

Kinetex Lab × Notion

Kaun Banega Codepati 2026

Problem Statements

Three challenges where Notion is the knowledge layer, turning scattered information into systems people can act on.

- ◆ **KBC-NOTION-01 Intelligent Campus Operating System**
- ◆ **KBC-NOTION-02 AI-Powered Project & Research Intelligence Workspace**
- ◆ **KBC-NOTION-03 Intelligent Team Operations & Event Command Center**

KBC-NOTION-01:- Intelligent Campus Operating System

Connecting campus knowledge, opportunities, tasks, people and decisions into one context-aware system.

Problem ID	Domain	Core constraint
KBC-NOTION-01	Technology	Notion must be meaningfully integrated

Problem statement

Campus information is scattered across announcements, student groups, club pages, forms, calendars, documents and personal notes. A student may get an event announcement in one channel, save its form elsewhere, note the deadline by hand, and later dig through several conversations to find it again. Student organizations face the same problem managing events, volunteers, speakers, registrations, documentation and follow-ups. Build a campus-level system that understands this fragmented information and turns it into structured, actionable knowledge, with Notion as the core collaboration and knowledge layer.

Objective

Develop a working Campus Operating System that organizes mixed campus information and converts it into personalized workflows for students, teams and organizations. It should keep relationships between events, people, clubs, opportunities, tasks, deadlines, resources and projects, instead of treating each record as an isolated item.

Mandatory functional requirements

- ◆ **Information structuring.** Turn unstructured announcements, notes or event descriptions into structured records with dates, owners, categories, requirements and actions.
- ◆ **Notion knowledge layer.** Create or sync Notion pages and databases and use them as an active part of the workflow.
- ◆ **Context-aware discovery.** Natural-language discovery across the user's authorized campus knowledge.
- ◆ **Personalized workflow.** Turn relevant information into tasks, reminders, saved opportunities or project actions.
- ◆ **Relationship and dependency mapping.** Represent links such as event → registration → task, club → event → volunteer, project → milestone → member.
- ◆ **Role-based experience.** Support at least two roles, such as student, club coordinator, event organizer or faculty mentor.

◆ **Analytics.** Show metrics such as pending registrations, deadlines, participation, workload or project progress.

Advanced challenge layer

- ◆ **AI extraction from noisy announcements and posters**
- ◆ **Permission-aware RAG over a Notion knowledge base**
- ◆ **Conflict detection for deadlines, events and team availability**
- ◆ **Opportunity recommendations based on declared interests and workload**
- ◆ **Automatic event lifecycle: announcement → registration → preparation → participation → documentation**
- ◆ **Explainable answers that show the source page or record**

Reference scenario

A club publishes a hackathon announcement. The system extracts the registration deadline, eligibility, venue and required actions, creates an event record and syncs it with Notion. A student saves the opportunity and gets preparation tasks. Later, the system answers “What do I need to complete before the hackathon?” from the student’s authorized workspace context.

Expected deliverables

- ◆ **Working web or mobile prototype**
- ◆ **Live Notion integration with pages and/or databases**
- ◆ **Architecture and data-flow diagram**
- ◆ **Source-code repository**
- ◆ **Demonstration dataset and Notion workspace**
- ◆ **Technical documentation and final pitch**

KBC-NOTION-02:- AI-Powered Project & Research Intelligence Workspace

From scattered research material and project discussions to traceable knowledge, tasks, decisions and deliverables.

Problem ID	Domain	Core constraint
KBC-NOTION-02	Education	Notion must be meaningfully integrated

Problem statement

Academic projects, hackathons and research teams produce problem statements, papers, datasets, experiment logs, meeting notes, decisions, tasks, code references and documentation, usually in disconnected documents and chats. As projects grow, teams lose track of why a decision was made, which experiment produced a result, which task depends on another, and which evidence supports a conclusion. Build an intelligent workspace that links project knowledge to execution, with Notion as the collaborative documentation and knowledge layer.

Objective

Build a research and project intelligence platform that organizes project knowledge, keeps traceable links between evidence and decisions, and turns discussions into an executable plan. It should support human-authored knowledge and AI-assisted organization without hiding the underlying sources.

Mandatory functional requirements

- ◆ **Knowledge ingestion.** Accept project notes, meeting records, references, experiment summaries or structured project data.
- ◆ **Traceable knowledge.** Keep links between source material, claims, decisions, tasks and outcomes.
- ◆ **Notion workspace automation.** Generate and update structured project pages and databases through the Notion integration.
- ◆ **Decision management.** Record decisions with rationale, owner, date and supporting evidence.
- ◆ **Experiment and task tracking.** Track experiments, milestones, tasks, outcomes and blockers.
- ◆ **Intelligent search.** Answer project-specific questions using authorized workspace context.
- ◆ **Project health view.** Surface stalled tasks, missing documentation, dependency chains and milestone status.

Advanced challenge layer

- ◆ RAG with source citations for project-specific answers
- ◆ Automatic conversion of meeting minutes into decisions, tasks and owners
- ◆ Evidence graph: references → observations → decisions → deliverables
- ◆ AI detection of contradictory project notes or stale documentation
- ◆ Automatic experiment summaries and weekly research reports
- ◆ Permission-aware collaboration between multiple project teams
- ◆ Change-impact analysis when a major decision is modified

Reference scenario

A research team uploads meeting notes describing three experiments and a new decision. The platform identifies the experiments, extracts action items, links the decision to its supporting notes, creates structured Notion records and assigns tasks. Later it answers “Which experiment supports our current approach?” with traceable source references, not an unsupported generated answer.

Expected deliverables

- ◆ Working project and research workspace
- ◆ Functional Notion API integration
- ◆ Sample project knowledge base
- ◆ Source and evidence traceability demonstration
- ◆ Architecture, API and data-flow documentation
- ◆ Live end-to-end demo and pitch

KBC-NOTION-03 :- Intelligent Team Operations & Event Command Center

An adaptive operations platform for managing complex events, teams, resources, dependencies and post-event knowledge.

Problem ID	Domain	Core constraint
KBC-NOTION-03	Productivity	Notion must be meaningfully integrated

Problem statement

Hackathons, conferences, technical fests and student-led events involve hundreds of actions: registrations, venue allocation, volunteer assignments, speaker coordination, task dependencies, schedules, communications, resources, judging and post-event reporting. Teams juggle spreadsheets, chat groups and ad-hoc documents, so a change in one area can silently affect others. A venue change, for example, can hit volunteer deployment, speaker timing, equipment needs and participant communication. Build a command center that represents these dependencies, with Notion as the operational knowledge layer.

Objective

Develop a system that helps event and team operators plan, run and document a complex event through a dependency-aware workspace. It should give one unified operational view while letting each team member work from a role-specific interface.

Mandatory functional requirements

- ◆ **Event planning model.** Represent schedules, venues, sessions, teams, participants, resources and responsibilities.
- ◆ **Dependency engine.** Model relationships between activities and identify downstream impact when a record changes.
- ◆ **Role-based command center.** Views for operations, technical, marketing, registration, volunteers or leadership.
- ◆ **Notion synchronization.** Keep operational records and documentation in Notion databases and pages.
- ◆ **Task and escalation system.** Track owners, deadlines, status, blockers and escalation conditions.
- ◆ **Live status dashboard.** Show what is completed, pending, blocked or at risk.

Post-event knowledge capture. Organize final reports, decisions, lessons learned and reusable documentation automatically.

Advanced challenge layer

- ◆ AI-based impact analysis after schedule or venue changes
- ◆ Automatic volunteer allocation by skills, availability and workload
- ◆ Real-time shift plans and escalation lists
- ◆ AI-generated daily operational briefings
- ◆ Risk detection from incomplete dependencies, overdue tasks or resource conflicts
- ◆ Post-event discussions converted into a reusable knowledge base
- ◆ Simulation mode to test schedule or resource changes before applying them

Reference scenario

An organizer changes the main auditorium two hours before the event. The system finds the affected sessions, equipment, volunteers and communication tasks, updates the operational workspace, writes an impact summary and assigns follow-up actions to the right roles. The final event report is then structured into a reusable Notion knowledge base.

Expected deliverables

- ◆ Functional event operations prototype
- ◆ Live Notion integration
- ◆ Dependency and impact demonstration
- ◆ Role-based dashboard
- ◆ Architecture and technical documentation
- ◆ Final live demonstration and presentation

How every problem is judged

The same evaluation parameters and constraints apply to all three problem statements.

Evaluation parameters

Parameter	Weight	Evaluation focus
Problem Understanding	15%	Clarity of user problem and proposed workflow
Innovation	15%	Originality and meaningful differentiation
Technical Implementation	20%	Engineering depth, architecture and reliability
Notion Integration	15%	Depth, usefulness and correctness of integration
Working Prototype	15%	Functional end-to-end demonstration
Feasibility & Scalability	10%	Practicality and ability to scale
Presentation & Demo	10%	Clarity, storytelling and live demonstration

Important constraints

- ◆ A simple Notion template, iframe, hyperlink or static page does not constitute meaningful integration.
- ◆ Teams may use any programming language, framework, database or AI model.
- ◆ Synthetic or demo data may be used where real institutional data is unavailable.
- ◆ AI-generated output should be distinguishable from verified source information.
- ◆ Teams must demonstrate the complete workflow during the final pitch.
